## ABSTRACT

This thesis describes the detailed design and implementation of a printer server in the laboratory environment of sharing resources among multiple Zenith Z-100 microcomputers. The Printer Server System is a controller box which consists of a power supply, a single board computer, and the BLC 8538 eight channel I/O expansion boards. Each Z-100 microcomputer is connected to the controller thru the RS-232C port.

The Printer Server System has three software utilities: BOOT, CONTROL and SPOOL. The BOOT process, resident in the controller, downloads the CONTROL file from any one of multiple Z-100's which is turned on. The CONTROL process allows the printer to be used by any one of multiple Z-100's at a time. The SPOOL process sends the data thru the CONTROL process to the printer or saves the data on the disk file.

#### ACKNOWLEDGEMENTS

We thank God for our health and patience. We are very grateful to a number of people for their help and encouragement.

Most of all, we would like to express our sincere appreciation to our thesis advisor, Professor Uno R. Kodres, for his enthusiastic guidance and support. Without his help and ideas about the program, this thesis could not have been completed. We also would like to say thanks to our second reader, Instructor Linda C. Rawlinson, for her helpful comments and her kindness.

We must thank to our wives, Young Mee Choi and Nam Yoen Lee, and our parents for their sincere help and encouragement during our studying period.

## I. INTRODUCTION

### A. GENERAL DISCUSSION

In a school or many companies, several personal computers are used on the same floor or the same room. Instead of having a printer with each personal computer, it is economical to share a high quality printer among many users. More generally, it is economical to share other high cost resources such as laser printers, Ethernet local area network controllers, high capacity disc units, among the personal computer users. It is the motivation to share expensive resources that has given rise to this thesis.

To design and implement a system which permits the sharing of a printer among twenty-three users, each user making use of a Zenith Z-100 personal computer, the hardware system, known as the Concentrator, consists of a MULTIBUS based backplane with an independent power supply, an INTEL iSBC 86/12A single board computer, three National Semiconductor BLC 8538 serial I/O expansion boards, all enclosed in a cardcage. The Zenith Z-100 personal computers are connected via their teletype ports(RS232 compatible) to the I/O ports of the Concentrator.

The software system consists of the Control Program, which is down-loaded from a Z-100 at power-up of the Concentrator and any Z-100 system, and which thereafter executes in the Concentrator permitting the shared use of the printer on a first-come first-serve basis.

The remaining software is a utility program, called SPOOL, which operates in the CP/M environment on the Z-100 and permits the user to store his interactive printer data on his disc unit, while the printer is busy printing another user's files.

The Control Program in the concentrator is implemented in assembly language. The CP/M operating system in the

Z-100 is modified by modifying the Basic Input/Output System (BIOS) of CP/M-85 for use for communication with the Concentrator.

The SPOOL program, also written in assembly code, allows the users to share the high speed printer in a batch mode, that is, each user prints out the files he desires, while any other user who wishes to make interactive use of the printer at the same time can save the information in his disk file for later batch printing. This permits an economical usage of a high cost resource without the inconvenience of long waits due to interactive use of the printer.

#### B. FORMAT OF THESIS

Chapter I gives an overview of this thesis. It also provides the general concepts and the construction of our system and explains why this thesis has practical value.

Chapter II explains the hardware basis of the system. Detailed information is given about all major hardware components which are used to construct the printer sharing system which is implemented in this thesis.

Chapter III describes the general structure of the CP/M operating system. The standard CP/M-85 operating system is discussed in moderate detail. Also covered is the modification of the CP/M-85 necessary to carry out the project.

Chapter IV explains the role and the structure of the Concentrator. Three utility programs, BOOT, CONTROL, and SPOOL, are explained in detail.

Chapter V summarizes the advantage of this system and indicates a direction for future research for microcomputer communication and networking using the local area network, Ethernet.

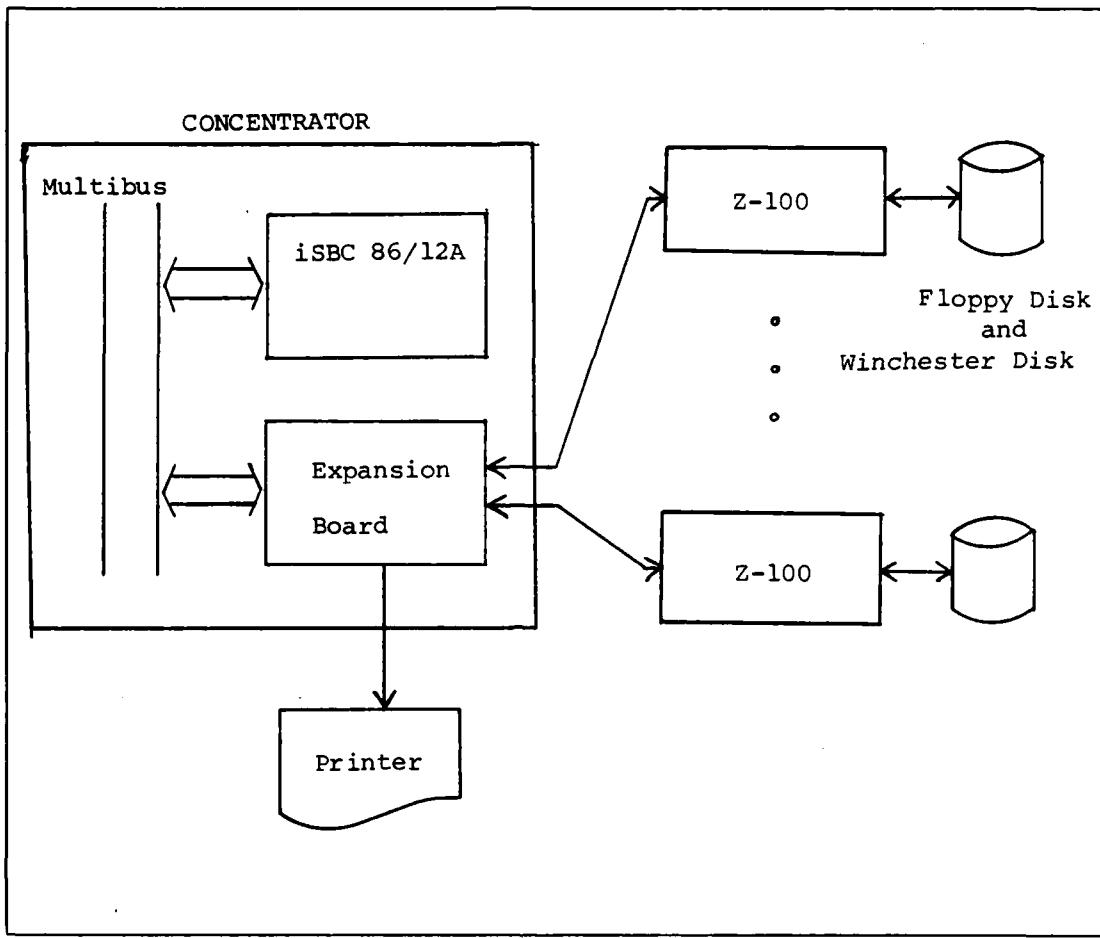

## II. HARDWARE BASIS OF THE SYSTEM

As stated in the introduction, the most important hardware components of this system are the iSBC 86/12A single board computer, the I/O expansion board, the multiple Z-100 microcomputers and the printer. Figure 2.1 depicts the interconnection of these components as they exist at this time. In the paragraphs which follow, a description of each component and its role in the overall system, is explained. A detailed description of each component can be found in the cited references.

### A. ISBC 86/12A SINGLE BOARD COMPUTER

#### 1. General Description

The iSBC 86/12A single board computer, which is a member of Intel's complete line of 8-bit and 16-bit single board computer products, is a complete computer system on a single printed-circuit assembly. This board includes a 16-bit Central Processing Unit(CPU), up to 32K bytes of Erasable Programmable Read Only Memory(EPROM), 64K bytes of Random Access Memory (RAM), a serial communications interface, three programmable parallel I/O ports, programmable timers, priority interrupt control, MULTIBUS interrupt control logic, and bus expansion drivers for interfaces with other MULTIBUS interface-compatible expansion boards. The systems view, however, is an abstract model, as systems exist only in the mind of the analyst. [Ref. 4: 1.1 - 1.3].

**Figure 2.1 System Configuration.**

## 2. Memory

The iSBC 86/12A board includes 64K bytes of read/write memory composed of sixteen 2117 Dynamic RAM chips and an 8202 RAM controller.

Four IC sockets are provided for user installation of EPROM chips, and jumpers are provided to accommodate either 2K, 4K, or 8K chips. The EPROM address space is located at the top of the 1-megabyte memory space because the 8086 CPU branches to FFFF0 after a reset.

This single board computer is used as the controller in the system. The control process of the Concentrator is loaded into the memory of this iSBC 86/12A single board

computer at the time of initialization of the system. The control process communicates to the multiple Z-100's and the printer, and receives or sends data from or to the devices. For the detail of the memory organization, see [Ref. 4: pp 4.2 - 4.3].

## B. INTEL 8086

The Intel 8086 is a high performance, general purpose 16-bit microprocessor. The 8086 is a full 16-bit processor with respect to both its internal structure, and its external connections. Refer to Figure 2.2 for a general overview of its internal structure and organization. This section is intended to give general knowledge about this device. A detailed description can be found in [Ref. 3].

### 1. Major Features of the 8086

In this section, we shall discuss the major features of the 8086 CPU chip. The 8086 has a 20-bit-wide address bus, providing it with the capability of addressing a full megabyte of memory. However, the address registers of the 8086 chip are only sixteen bits wide. This is equivalent to only sixty four kilobytes. This processor uses a method called segmentation to allow smooth access to the whole megabyte of address space. The twenty bit physical address is formed, by adding a sixteen bit offset to a twenty bit address whose most significant sixteen bits come from a sixteen bit segment register.

### 2. Registers

The 8086 contains fourteen 16-bit registers. Some of these belong to the EU(Execution Unit) and others belong to the BIU(Bus Interface Unit). The EU registers tend to be general-purpose registers, whereas the BIU registers tend to be used for addressing. There are eight 16-bit general purpose registers. Four of these are byte or word addressable and are referred to as the 'data group'. The remaining four are only word addressable and are referred to

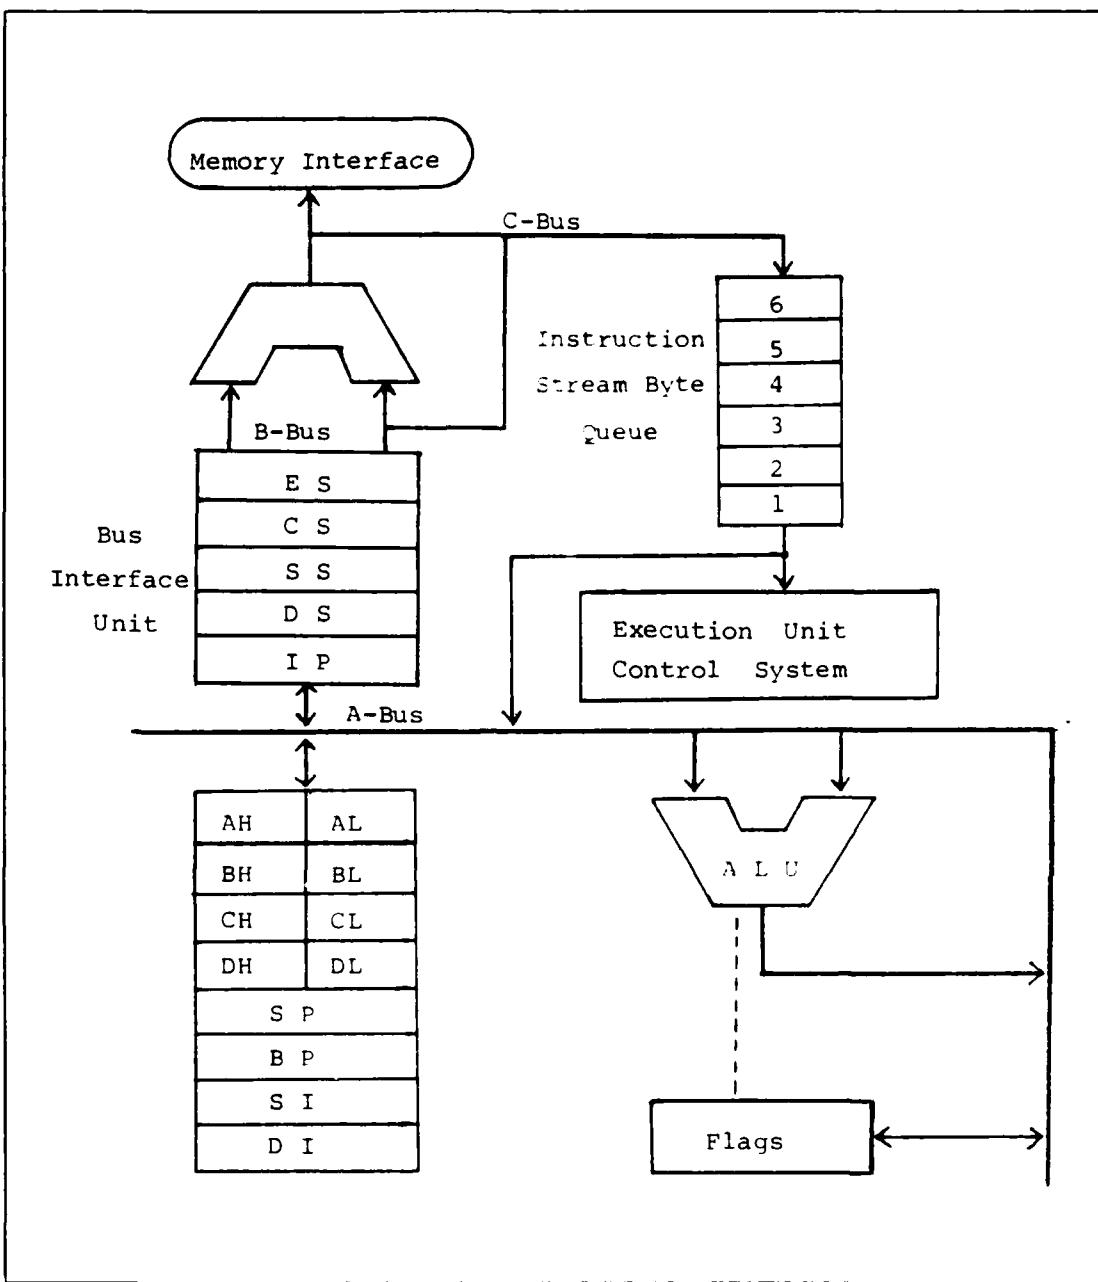

Figure 2.2 Functional Structure of 8086.

as the pointer and index register, SP, BP, SI, and DI, which cannot be further subdivided.

SP is the stack pointer, BP is the base pointer and SI and DI are named the source and destination index register, respectively.

The flags register is sixteen bits wide and consists of nine usable status bits for the processor. These include : zero flag(ZF), direction flag(DF), interrupt flag(IF), overflow flag(OF), and trap flag(TF).

The BIU has the remaining registers : four segment register, CS, DS, SS, and ES. These stand for the code, data, stack, and extra segment register respectively, and one instruction pointer(IP).

#### C. COMMUNICATION EXPANSION BOARD

This expansion board is used to connect the multiple Z-100 computers and the printer to the single board computer of the Concentrator. We can connect from fifteen to twenty three Z-100 microcomputers with two or three BLC 8538 eight channel communication expansion boards. The BLC 8538 eight channel communication expansion board provides fully programmable synchronous or asynchronous serial communication channels with RS232C interfaces to expand system serial communications capability. Each individual channel provides two interrupt requests with distinct priorities. The BLC 8538 is compatible with all National Semiconductor Serial 80 cardcages, back planes and microcomputer system bus structures.

The universal synchronous and asynchronous receiver/transmitter(USART) control logic block gates the data on the data bus to the appropriate USART reset pins. Writing to the USART reset logic register resets each USART displaying a logic one on its corresponding data line. Two 74LS08 and gate devices gate the data bus to the appropriate USART reset pins. Data lines zero thru seven(DA0-DA7) are logically ANDed with the reset I/O line. Writing to the reset register causes each set data bit in the USART control logic to reset its corresponding USART.

A USART reset causes the following :

- a) Resets status bits to zero,
- b) Disables the transmitter and receivers,
- c) Clears any interrupt requests,
- d) Clears the mode, status and command registers.

The USART's function is to transmit eight (or less) bits of data on one signal wire in a serial fashion to another USART. The other USART assembles the serial bit pattern into an eight bit value transferrable to the data lines of a data bus of a computer. Each USART uses four address locations : one as a data register, one as a control register, one as mode selection register, and one as a status register. The 2651 has nine 8-bit registers that can be written to and/or read from by the system CPU through the data bus D7-D0. The nine 8-bit registers are mode register 1, mode register 2, command register, status register, SYN1/SYN2/DLE registers, and transmit/receive data holding registers.

The 2651 USARTs must be programmed by the system CPU before transmitting or receiving data. Programming the USART consists of four steps. First, the user should reset the USART. Second, the user writes to the Mode Register 1. On the third step, the user writes to the Mode Register 2. Finally, the user writes to the Command Register. The registers are described in detail below.

1. Mode Register 1

This register sets the mode(synchronous or asynchronous), parity use and type, character length, and other parameters. The register format is shown in Figure 2.3. In our program, the programming code will be 01001110B(4EH).

## 2. Mode Register 2

This register sets the baud rate and the external/internal characteristic of the transmitter and receiver clocks. The register format is shown in Figure 2.4. The programming code will be 00111110B(3EH).

MR1-7	MR1-6	MR1-5	MR1-4	MR1-3	MR1-2	MR1-1	MR1-0
sync:	sync:	parity type	parity control	character length		mode and baud rate factor*	
				00=5 bits			
no. of syn chars	transp- syn control	0=odd 1=even	0=disabled 1=enabled	01=6 bits 10=7 bits 11=8 bits		00=sync 1x rate 01=async 1x rate 10=async 16x rate 11=async 64x rate	
0=double syn 1=single syn	0=normal 1=trans- parent						
async:stop bit length				*baud rate factor in asynchronous mode applies only if external clock is selected. Factor is 16x if internal clock is selected.			
00=invalid							
01=1 stop bit							
10=1½ stop bits							
11=2 stop bits							

Figure 2.3 Mode Register 1 Format.

## 3. Command Register

This register controls the DTR (Data Terminal Ready) and RTS (Request to Send Data) outputs, operating mode, transmit control enable and receive control enable. The register format is shown in Figure 2.5. The command register can be written to, but not read from. The programming code will be 00000111B(07H).

MR2-7	MR2-6	MR2-5	MR2-4	MR2-3	MR2-2	MR2-1	MR2-0
not used	transmi- tter	receiver clock		baud rate	selection		
		clock		0000=50 baud	0001=75 baud		
				0010=110 baud	0011=134.5 baud		
0=	0=	0100=150 baud		0101=300 baud			
		0110=600 baud		0111=1200 baud			
		external external	1000=1800 baud	1001=2000 baud			
l=	l=	1010=2400 baud		1011=3600 baud			
		internal internal	1100=4800 baud	1101=7200 baud			
			1110=9600 baud	1111=19200 baud			

Figure 2.4 Mode Register 2 Format.

#### 4. Status Register

The status register indicates the state of the TxRDY (Transmitter Ready Interrupt) and RxRDY (Receiver Ready Interrupt) outputs and the DCD (Data Carrier) and DSR (Data Set Ready) inputs. The register format is shown in Figure 2.6. The status register can be read from, but not written to. If the Transmitter is ready, the code will be 00000001B(01H). If the Receiver is ready, the code will be 00000010B(02H).

#### 5. SYN1/SYN2/DLE Registers

If synchronous operation is chosen, these three registers must be loaded to provide characters for synchronization, idle, fill, and data transparency. The use of these characters is governed by the mode into which the USART is programmed. For example, bits 6 and 7 of Mode Register 1 control the number of SYN characters used and the transparency mode. These registers are not used in this application.

## 6. Transmit/Receive Data Holding Registers

These two registers share the same address. When transmitting, the system CPU writes a data word to the Transmit Data Holding Register so that it can be serialized and transmitted. When receiving, the system CPU reads from the Receive Data Holding Register to receive the data word that has been received and deserialized. The detail of USART can be found in [Ref. 10: pp. 3.7 - 3.16].

### III. SYSTEM SOFTWARE

An operating system is any program or group of related programs whose purpose is to act as an intermediary between the hardware and the user of a computer. In the case of a small microcomputer application, the operating system may consist of little more than a set of service routines and a simple set of commands that allows the user to load or dump memory to or from an external storage device, to modify bytes, and to test application programs.

A more sophisticated operating system may have a disk-controller interface and some form of memory management. The highest level of operating system includes such features as multiprogramming, bank-selected memory, a hard-disk controller interface, and random track-sector allocation. CP/M (Control Program for Microcomputers) is typical of a class of operating systems for the microcomputers currently in widespread use.

This chapter describes the structure of CP/M-85 operating system for the Z-100 microcomputers and some modifications to it.

#### A. CP/M-85 OPERATING SYSTEM

##### 1. General Discussion

CP/M-85 operating system for the Z-100 microcomputer is divided into two software components: the "system kernel" and the "BIOS files".

The system kernel is a set of programs that reside on the reserved system tracks of a disk. Special data transfer utilities (usually SYSGEN and/or MFCPM207) are used to copy the system kernel from one disk to another. The system kernel manages files, translates the commands you

enter at the keyboard, and performs other functions that do not depend upon specific hardware characteristics.

CP/M-85 BIOS consists of two files, BIOS85.SYS and BIOS88.SYS, which reside on the file tracks of the disk. The portion of the BIOS stored in the file BIOS85.SYS uses the 8085 processor of the Z-100. The portion stored in BIOS88.SYS uses the 8088 processor of the Z-100. For further information on the CP/M-85, refer to [Ref. 7: pp 1.9 - 1.10].

## 2. Structure

CP/M is logically divided into four parts, called the Basic I/O System (BIOS), the Basic Disk Operating System (BDOS), the Console Command Processor (CCP), and the Transient Program Area (TPA). The memory organization of the CP/M system is in the Figure 3.1.

### a. Basic Disk Operating System (BDOS)

The BDOS is responsible for all management functions including disk-file management, I/O high-level management, and all other function calls available to the user. The BDOS makes calls to the BIOS, which interfaces with the actual hardware environment of the microcomputer. For the detail of the BDOS functions, see [Ref. 12: p. 140]. and [Ref. 8: pp. 124 - 125].

Our SPOOL program will use some of the BDOS functions: List Output, Make File, Write File, Close File, and so on. The List Output function is activated by pressing Control-P key, which copies everything that appears on the screen to the printer.

Access to a file on the disk is done through an File Control Block (FCB). An FCB is supplied for each file the user wishes to access. The detailed description of FCB is found in [Ref. 8: pp. 93 - 94].

b. Basic I/O System (BIOS)

The BIOS is a hardware-dependent module that defines the exact low level interface with a particular computer system that is necessary for peripheral device I/O. The BIOS is a collection of user-written subroutines for primitive character I/O and disk access. Disk functions include: set DMA address, set track and sector, read sector, write sector and so on. A series of jump vectors is located at the head of the BIOS and points to all internal subroutines. The BDOS locates subroutines in the BIOS by calling the subroutines at the known location in the jump vector area.

c. Console Command Processor (CCP)

When CP/M becomes active, it gives control to the CCP, which, is actually an application program loaded at the top of the TPA. When first entered, the CCP displays a prompt character, 'A>'. This indicates which disk drive is currently logged in for use. To change drives, the user simply enters the drive name and a colon (for example, B:). This causes the CCP to request the BDOS function call "select disk," with register E containing a number representing the requested drive (A=1, B=2, and so forth). There are five built-in commands: TYPE, DIR, REN, ERA, and SAVE. A number of transient commands are also provided: SYSGEN, PIP, ED, ASM, DUMP, LOAD, STAT, MOVCPM, SUBMIT, and DDT. These commands are actually .COM files or memory image files. For the detail of the CCP operation, see [Ref. 12: pp. 148 - 149].

d. Transient Program Area (TPA)

The TPA is an area of memory (i.e., the portion that is not used by the FDOS and CCP) where various nonresident operating system commands and user programs are executed. The lower portion of memory is reserved for system information. For the detail about the memory organization, see [Ref. 8: pp 89 - 90 ].

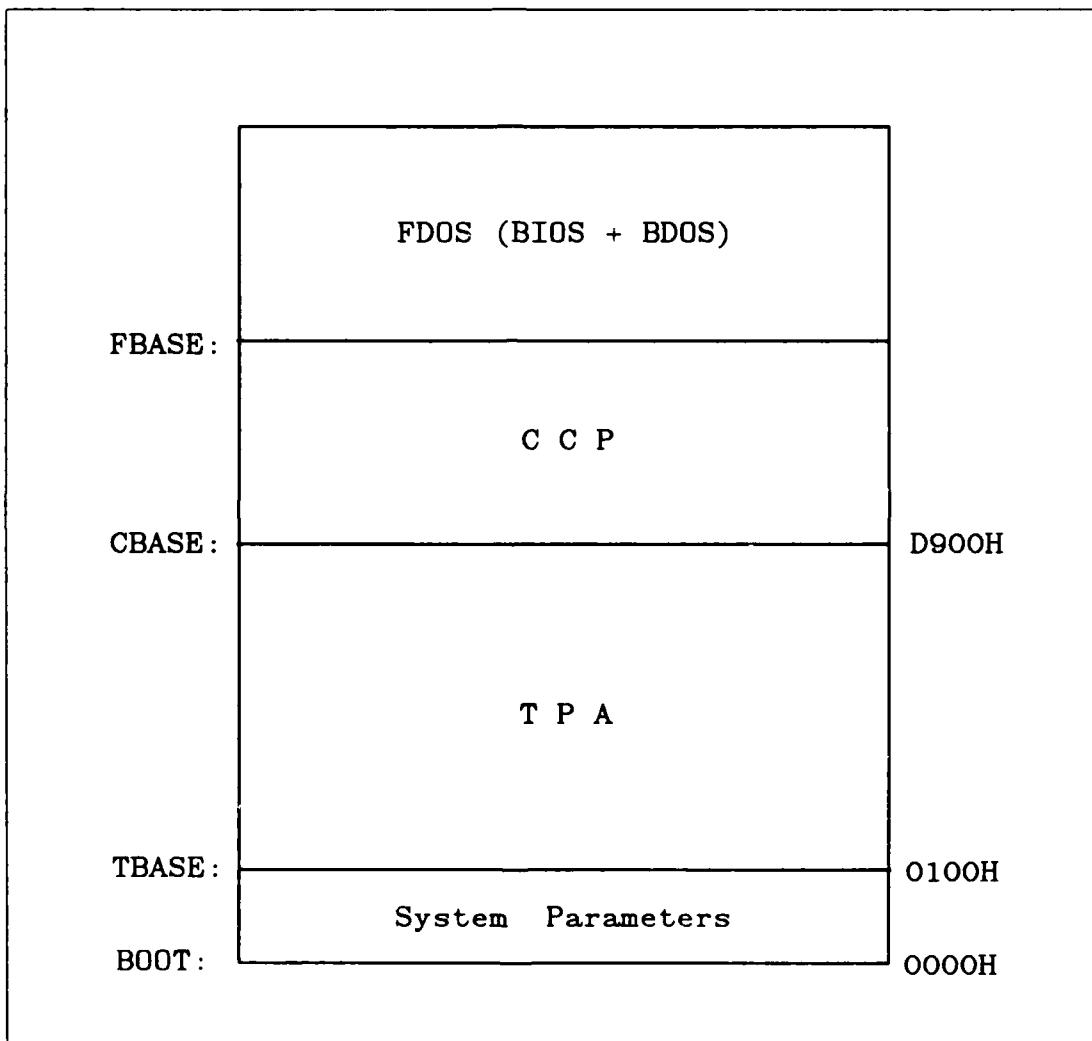

Figure 3.1 Memory Organization of CP/M.

## B. MODIFICATION TO CP/M-85 BIOS

Since the SPOOL utility program uses the List Output function as described in the previous section, we should intercept some point of the List Output function routine in BIOS. The BIOS85.SYS file could be modified by using the DDT debugging utility.

The BIOS entry point of List Output function is located at F93DH. This is shown in the Figure 3.2 a. We patch this point so that the List Output function pass through a certain intercept program in the TPA area to the BIOS. It's necessary to place the intercept routine at an area of the TPA that is near to the BIOS. Since the BIOS starts from D900H, we place the interrupt program at D800H. The interrupt program is contained in the SPOOL utility program. When the user activates the SPOOL program, the intercept routine is also loaded at D800H.

The List Output function is activated by pressing the Control-P key. When the user press the Control-P key, everything on the screen is caught and loaded into E register and then sent to the printer. The intercept routine is intended to intercept the character in E register and provide the SPOOL utility program with that character. The detail of this mechanism is discussed in the next chapter.

#### IV. IMPLEMENTATION OF THE SYSTEM

This chapter describes the structure of the Concentrator, the connection between the Concentrator and Z-100's, and the logic designs of three processes. In the last section of the chapter, we address the integrated operation of the processes.

##### A. STRUCTURE OF THE CONCENTRATOR

The structure of the Concentrator is shown in Figure 4.1. The Concentrator consists of one iSBC 86/12A single board computer and three BLC 8538 eight channel I/O expansion boards. They are connected to the MULTIBUS so that the single board computer could access any channel of the three expansion boards. Since each expansion board has eight channels, the Concentrator can have twenty four channels. Each channel of the expansion board could be connected to one peripheral device. Therefore, the Concentrator can control twenty four peripheral devices. In our design, the printer is connected to the Channel zero, and the other twenty three channels are connected to the TTY ports of Z-100's. Each channel is associated with a Universal Synchronous Asynchronous Receiver Transmitter(USART), which contains four registers: Data, Status, Mode 1, Mode 2, and Command registers. The details about programming the USART are in the Chapter 2. For more information about the address assignment of the registers, see [Ref. 10: pp. 3.3 - 3.11].

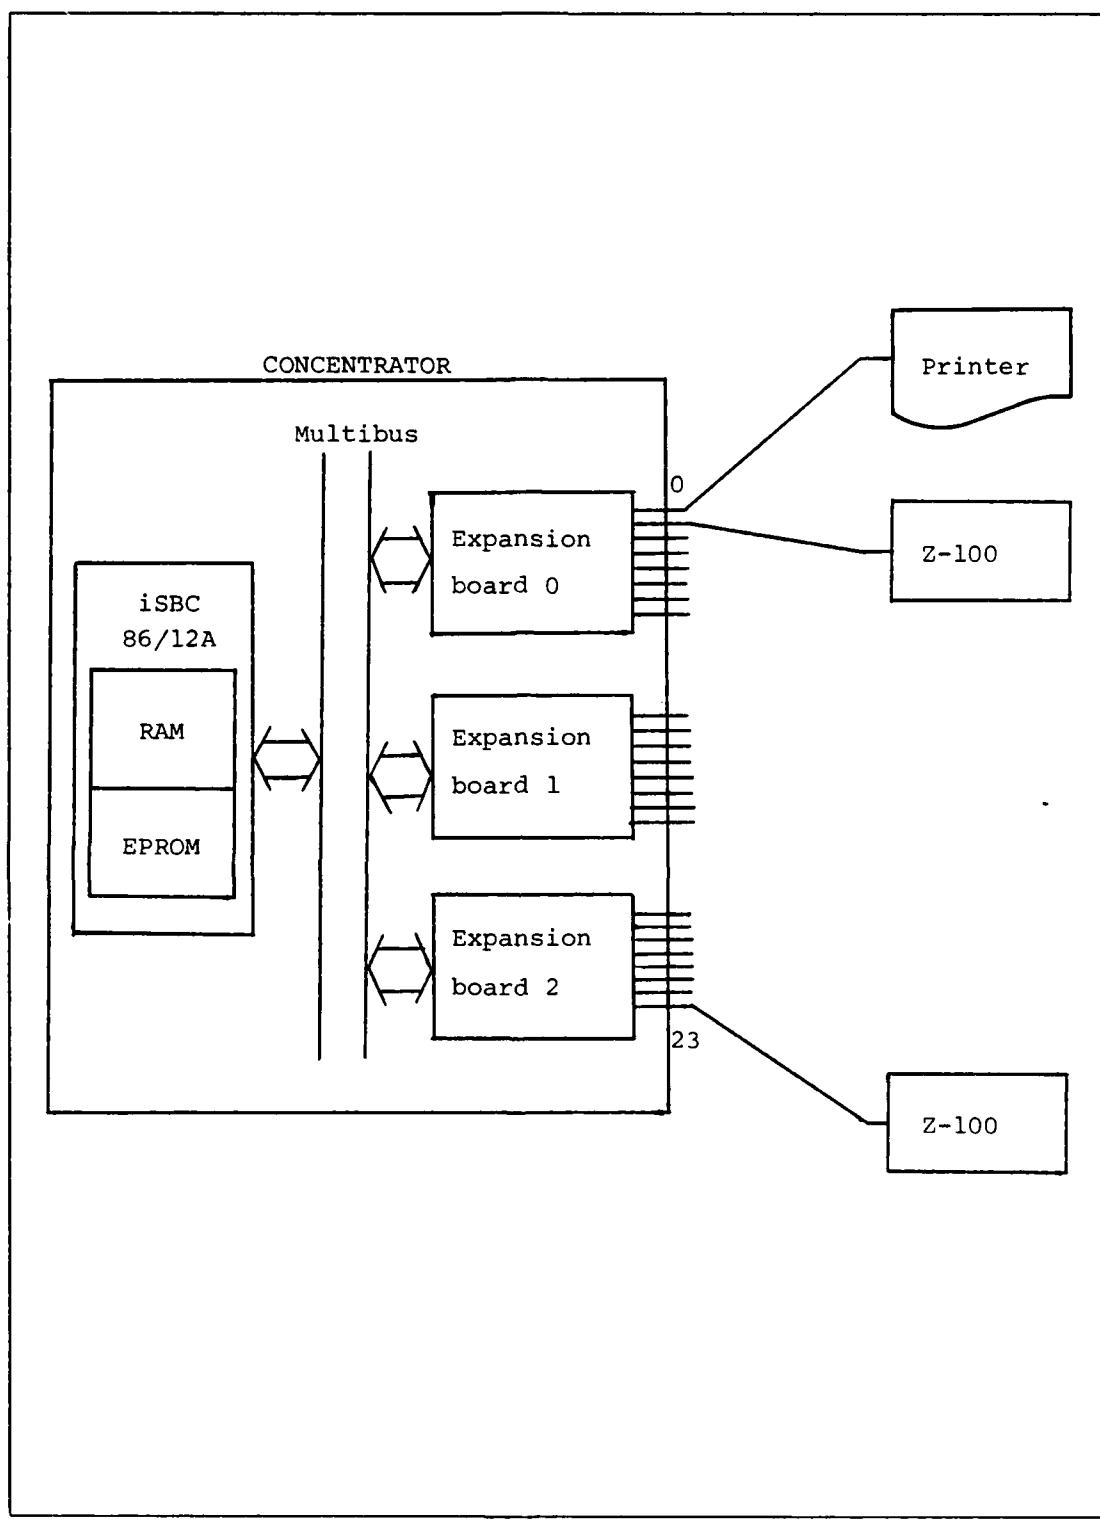

Figure 4.1 Structure of the Concentrator.

## B. BOOT PROCESS

The function of the BOOT process is to download the CONTROL process from any Z-100 into the RAM of the single board computer. The logical flow of the BOOT process is shown in Figure 4.2 and the algorithm of the BOOT process is in Figure 4.3. When the Concentrator is turned on, the BOOT process inside the EPROM of the iSBC 86/12A starts to check the status ports of the multi-channel expansion boards in a round robin fashion to check if a Z-100 is turned on or not. Since the CONSOLE of Z-100 is assigned to the TTY port, the Z-100 will send a message terminating with 'A>' to the dedicated port of the expansion board when it is turned on. The BOOT process will send a command 'TYPE A:CONTROL.CMD' to down-load the CONTROL process when it reads in the 'A>'. Then, the Z-100 will send the CONTROL.CMD file to the Concentrator while the BOOT process reads in the file and stores it in the RAM. Because the TYPE function of the CP/M operating system stops printing the file when it meets a Control-Z character, we have taken another character, the percentage '%', to signal the end of file.

On the completion of downloading the CONTROL.CMD file, the CONTROL process is executed. The CONTROL process issues the reset command 'STAT CON:=CRT:', which changes the CONSOLE device from TTY to CRT. Then, 'A>' will appear on the screen of the Z-100 and the user of the Z-100 can do his work. From now, the CONTROL process starts to communicate with the printer and the multiple Z-100 microcomputers. The program listing of the BOOT process is in APPENDIX A.

## C. CONTROL PROCESS

The function of the CONTROL process is to control the printer and multiple Z-100's and to connect the printer to any one of the multiple Z-100's at a time so that the data could be transferred from Z-100 to the printer. The purposes of the CONTROL process are:

- 1) To allow use of the printer for any connected Z-100.

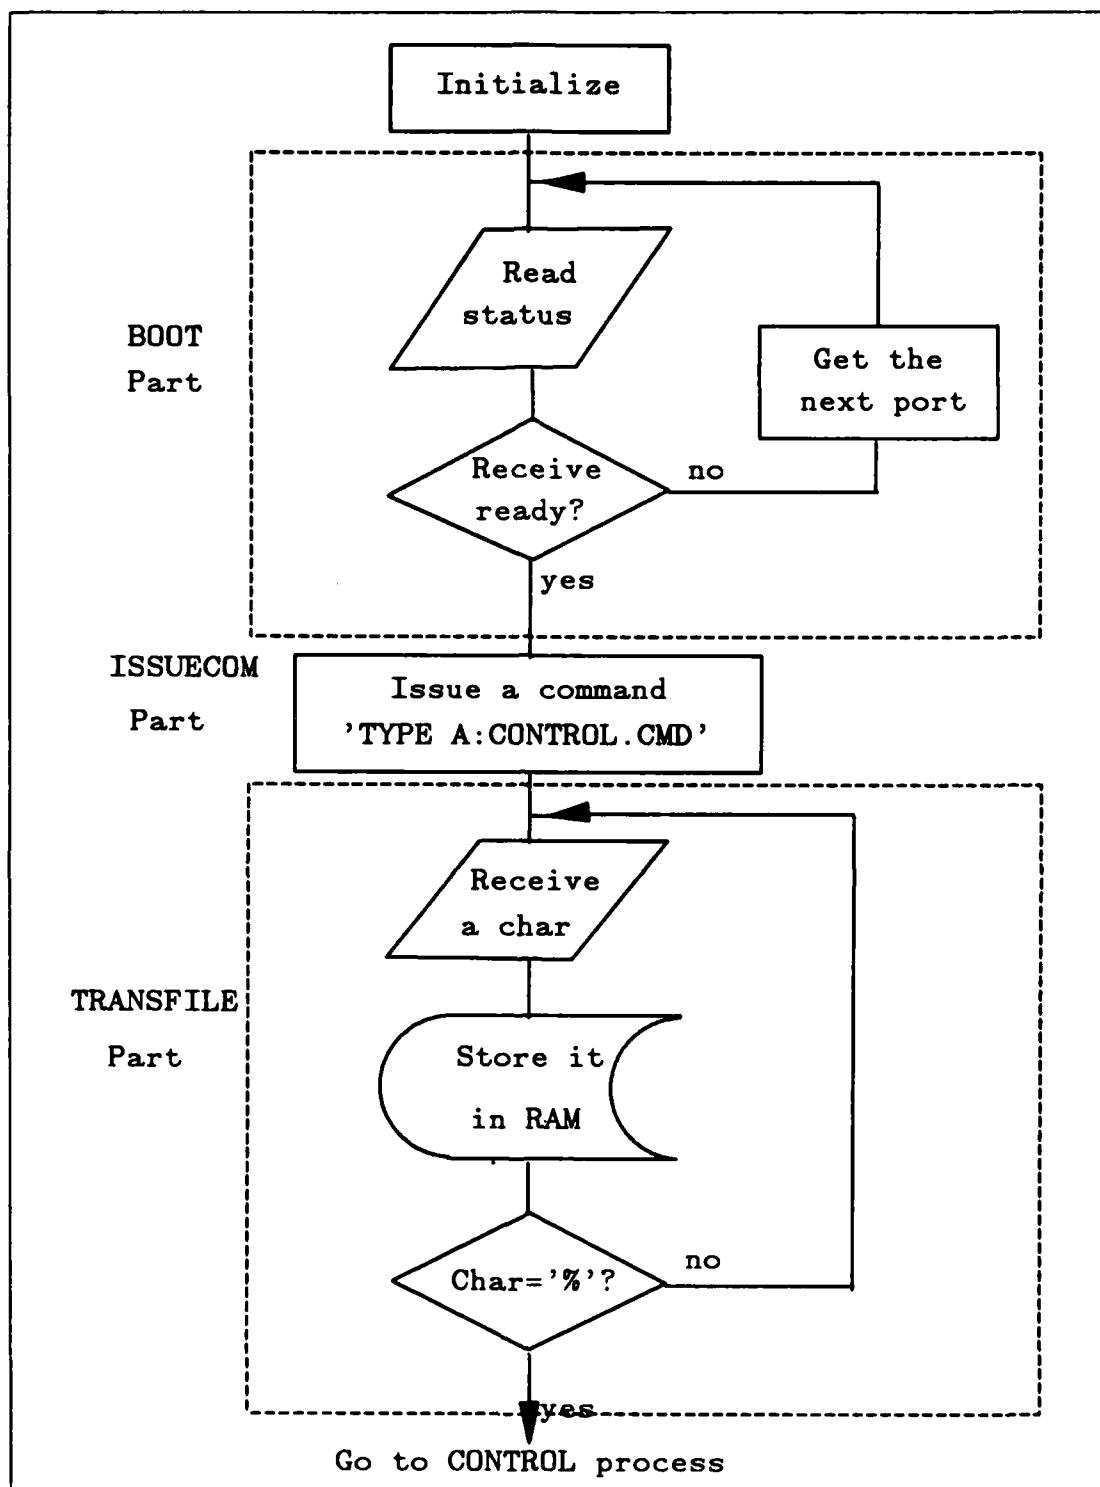

Figure 4.2 Logical Flow of BOOT.

### Algorithm of BOOT Program

\*\*\*\*\* Initialization \*\*\*\*\*

Initialize the USARTs

Set PORTNO with the first status port

\*\*\*\*\* BOOT Part \*\*\*\*\*

Repeat

    Read the status port given by PORTNO

    If the port is Receive-ready

        then read a character from the data port

        If the character is '>'

            then go to ISSUECOM part

        else store the next status port into PORTNO

Until the control is sent to the ISSUECOM

\*\*\*\*\* ISSUECOM Part \*\*\*\*\*

Set the command string with 'TYPE A:CONTROL.CMD'

Call COMMAND

\*\*\*\*\* TRANSFILE Part \*\*\*\*\*

Repeat

    Read a character from the data port

    Store the character into the new code area

Until the character is '%'

Execute the CONTROL program

\*\*\*\*\* Subroutine COMMAND \*\*\*\*\*

Send the command string to the Z-100

Figure 4.3 Algorithm of BOOT.

- 2) To permit any Z-100 to be activated, even during the time that the printer is in use.

The logical flow of the CONTROL process is shown in Figure 4.4 and the algorithm of the CONTROL process is in Figure 4.5.

The CONTROL process is stored in CONTROL.CMD file of all Z-100's. The CONTROL.CMD file, however, is downloaded into the RAM of the single board computer when the Concentrator and the first of the Z-100's is turned on. The CONTROL process is composed of two states: the control state and the transfer state. The CONTROL process lies in one of two states at a time. When the CONTROL process is in the control state, it checks the status ports of the multi-channel expansion boards in a round robin fashion to see if any boot or print request is issued from a Z-100. If a channel has a request, the CONTROL process reads in the character from the data port of the channel. The character sequence 'Q' means a print request and 'A>' means a boot request. On receiving the character 'Q', the CONTROL process sends a confirm character 'Y' to the Z-100 and then goes to the transfer state. In the transfer state, the CONTROL process receives a character from Z-100 and sends it to the printer using a software handshaking method. The CONTROL process checks all the other ports whenever one hundred and twenty eight characters are sent to the printer to know if they want to boot-up. For every port which wants to boot-up, it issues the command 'STAT CON:=CRT:', and then continues to print the characters in the transfer state. After that, the Z-100 which has received the reset command can work its own job. The CONTROL process stops its transfer of data between the Z-100 and printer when it reads in a Control-Z (end-of-file) character, and then enters the control state to check the next status port.

When the CONTROL process reads in 'A>' in the control state, it issues a reset command 'STAT CON:=CRT:' because

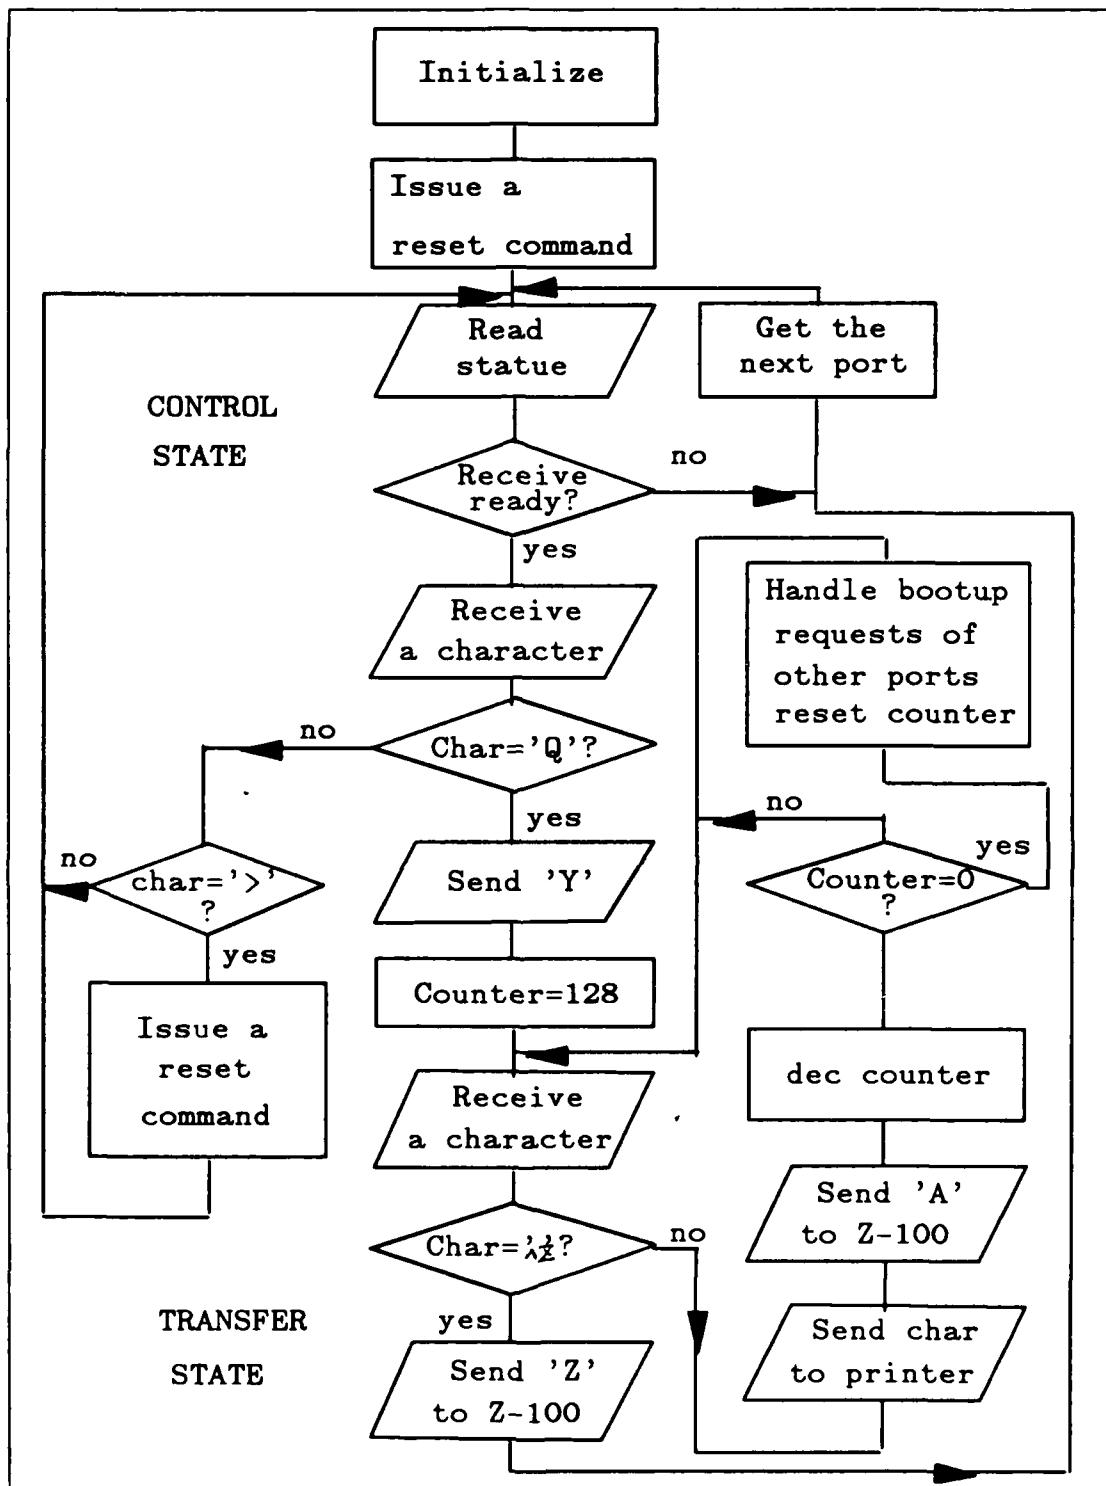

Figure 4.4 Logical Flow of CONTROL.

### Algorithm of CONTROL Program

```
***** Initialization *****  
Set PORTNO with the first status port  
Call RESET

***** CONTROL Part *****  
Repeat  
    Read the status port given by PORTNO  
    If the port is receive-ready  
        then read a character from the data port  
        If the character is '>'  
            then call RESET  
        else if the character is 'Q'  
            then go to TRANSFER  
        else store the next status port into PORTNO  
Until the system control is sent to the TRANSFER

***** TRANSFER Part *****  
Repeat  
    Read a character from the data port of Z-100  
    Send the character to the printer port  
    Call BCHECK on every 128 characters  
Until meet the End-Of-File mark '^Z'  
Go to CONTROL

***** Subroutine COMMAND *****  
Send the command string to the Z-100

***** Subroutine BCHECK *****  
Check all other status ports once  
For each port which has the boot-up request  
call RESET
```

Figure 4.5 Algorithm of CONTROL.

there is no need for downloading the CONTROL.CMD file. On receiving other characters than 'Q' or 'A>', the CONTROL process ignores them and goes to the next port to check.

Program listing of CONTROL process is in APPENDIX B.

#### D. SPOOL PROCESS

The SPOOL process has three functions. It also has the intercept routine for intercepting the List Output function of the BIOS. The intercept routine is really a part of the List Output function of the BIOS. The intercept routine receives the control from the List Output function and calls the SPOOL program, and then returns the control back to the List Output function of the BIOS. The mechanism between the List Output function and the SPOOL program is explained below.

The SPOOL process has three options, they are:

1. Send the characters on the screen of a Z-100 directly to the printer.
2. Save the characters on the screen of a Z-100 into a disk file.
3. Print any existing disk file.

The logical flow of the SPOOL process is shown in Figure 4.6 and the algorithm of the SPOOL process is in Figure 4.7.

The user can select any one of the above options by typing in the appropriate digit corresponding to the selection. Each function is implemented with a pair of modules: Set and Path. Function 1 is composed of Set1 and Path1, Function 2 is composed of Set2 and Path2, and Function 3 is of Set3 and Path3.

The entry point on the head of the SPOOL program is composed of a selection routine which jumps to one of 3 Path modules depending on the user's selection number.

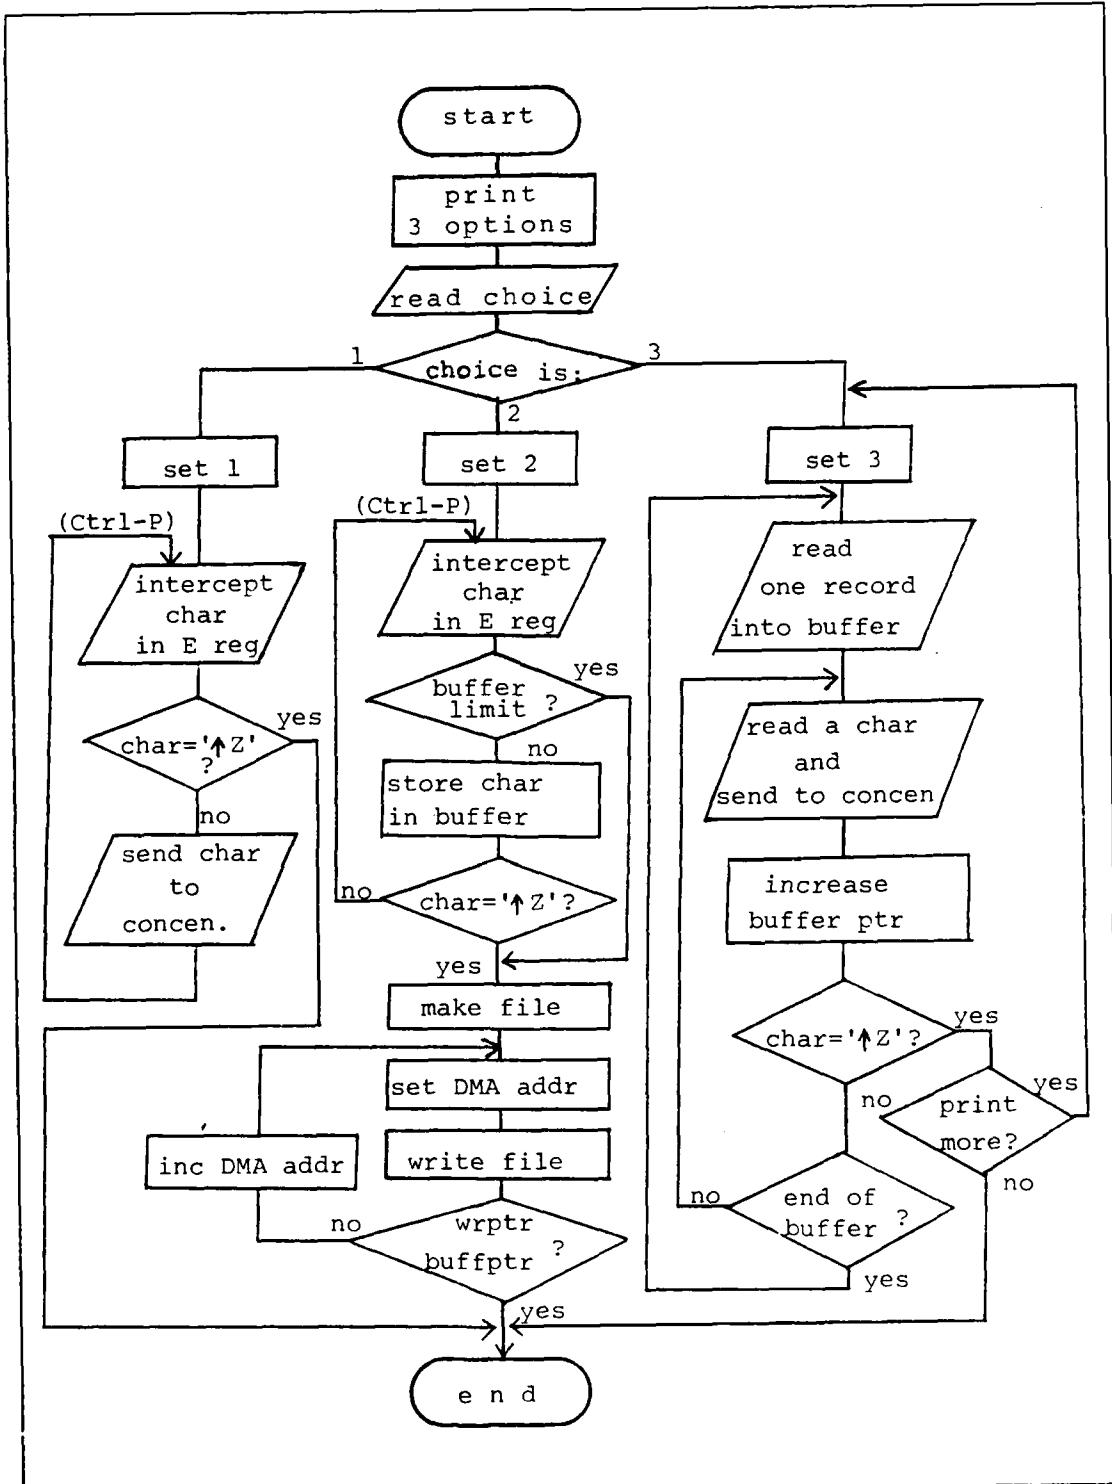

Figure 4.6 Logical Flow of SPOOL.

### 1. Function 1

Function 1 sends the character on the screen directly to the printer through the Concentrator in Ctrl-P mode. When the user selects Function 1, Set1 module sets the buffer pointer with its own buffer address and the path-flag with number one. Then the buffer pointer contains the starting address of the buffer whose size is 128 bytes and the path-flag contains number one. On the completion of setting the buffer pointer and path-flag, Function 1 comes out to the CCP level, printing a message that user should press the Ctrl-P key and go ahead. As the user hits Ctrl-P key, the List Output routine calls the address of entry point (D000H) of the SPOOL process whenever a character is typed in. Since the path-flag is set with number one, Path1 is then activated. Path1 reads in the character in the register E which is captured by the List Output function, and then sends the character to the Concentrator. The Function 1 returns the control back to the List Output function. Function 1 repeats this process until the user hits the Ctrl-Z key. When the user hits the Ctrl-Z key, Function 1 comes out to the CCP level.

### 2. Function 2

Function 2 is similar to Function 1 except that Function 2 saves the character in a disk file while Function 1 sends the character to the printer directly. When the user selects Function 2, Set2 module sets the buffer pointer with the buffer address and the path-flag with number one. Set2, also, reads in user-specified file name. If, however, user does not specify his/her own file name, default file name (TEMPFILE.\$\$\$) is used. On the completion of setting the buffer pointer, path-flag, and reading in the file name, Function 2 comes out to the CCP level, printing a message that the user should press the Ctrl-P key and go ahead. As the user hits Ctrl-P key, the List Output routine calls the address of entry point, which activates Path2. Path2 reads

## Algorithm of SPOOL

\*\*\*\*\* Initialization \*\*\*\*\*  
The user selects one of the three options  
Go to the corresponding SET module  
Each SET module goes to the corresponding PATH module

\*\*\*\*\* PATH 1 \*\*\*\*\*  
Repeat  
    Read a character from the Z-100  
    Store the character into the buffer  
    Send the character to the printer  
Until it meets the End-Of-File mark '^Z'  
Go to the CCP level

\*\*\*\*\* PATH 2 \*\*\*\*\*  
Call READNAME  
Repeat  
    Read a character from the Z-100  
    Store the character into the buffer  
Until it meets the End-Of-File mark '^Z'  
    or the buffer limit  
Make a file  
Write the file  
Close the file  
Go to the CCP level

\*\*\*\*\* PATH 3 \*\*\*\*\*  
Call READNAME  
Repeat  
    Read a record from the file  
    Send the record to the printer  
Until it meets the End-Of-File mark '^Z'  
Go to the CCP level

\*\*\*\*\* Subroutine READNAME \*\*\*\*\*  
Read a file name from the console

Figure 4.7 Algorithm of SPOOL.

in the character in register E which is captured by the List Output function, and then store it in the buffer while the buffer pointer is incremented. And then Function 2 returns the control back to the List Output function. Path2 repeats this process until the user hits the Ctrl-Z key. Path2 stores the Ctrl-Z character on the end of the buffer when it meets the Ctrl-Z character. After that, Path2 makes a file and write the file with the content of buffer by one record(128 bytes) at a time. We use 2 pointers, the write pointer and the buffer pointer, during writing the file. Buffer pointer points to the address of the last character in the buffer while write pointer is set with the starting address of the buffer. Whenever a record is written in the file, the write pointer is increased by 80H. Write process is done when the write pointer becomes greater than the buffer pointer. Since the buffer size is not large enough for a big file, when the buffer pointer exceeds the limit Function 2 will issue a message that the buffer is full and the user may take an action to reset the pointers.

### 3. Function 3

Function 3 reads a file whose file name is given by user and sends the contents of file to the printer through the Concentrator. Function 3 reads in one record of the file at a time and repeats this until it meets the Ctrl-Z character. The buffer is the same one of Function 1. Once reading one record into the buffer, Function 3 sends the content of buffer one byte at a time to the printer thru Concentrator. Function 3 does not need the Ctrl-P function while function 1 and 2 use it. Program listing of SPOOL process is in APPENDIX C.

## V. CONCLUSIONS

The primary goal of this thesis was met. The CONTROL process was designed for the communication with the multiple Z-100 microcomputers and the printer, and this is successfully integrated into the Printer Multiplexing System with the SPOOL utility program. The BOOT process was designed for downloading the CONTROL process from any one of the Z-100's, which eliminated the need for the disk drive, console and/or additional EPROM to store the CONTROL process.

This system allows use of the printer for any connected Z-100, permits interactive use of the printer to one user when nobody else is waiting to use it, and enables the effective interactive sharing of the printer among multiple users by spooling any character on the screen into a disk file for later batch printing.

Future research involving the Printer Multiplexing System should develop the 8086 code of the SPOOL utility program so that the users could use the SPOOL in the environment of CP/M-86 or MS-DOS. The BOOT and CONTROL processes are already written in the 8086 code.

Additionally, we are expecting that this system could be integrated into the Ethernet. Then the CONTROL process should be expanded to contain the Ethernet protocol program.

APPENDIX A  
USER MANUAL FOR PRINTER SHARING

A. SYSTEM CONFIGURATION

The Printer Sharing system consists of one iSBC 86/12A single board computer, three BLC 8538 I/O expansion boards, the multiple Z-100 microcomputers, and the printer. The detail about the iSBC 86/12A single board computer and the BLC 8538 I/O expansion boards can be found in the Chapter 2.

B. ACTIVATING THE SYSTEM

Turn on the Concentrator before any Z-100 microcomputer is turned on. The user should keep this power-up procedure because the BOOT program needs to initialize the USART before checking the ports of the I/O expansion boards. At this time, the CONSOLE device of the Z-100 is normally assigned to the teletype port. Otherwise, the user should change the CONSOLE device of the Z-100 computer to the teletype port manually. And then, the CONTROL.CMD file in drive A is down-loaded into the RAM of the single board computer. When the CONTROL program begins to execute, it changes the CONSOLE device to the standard device CRT. Then, the Z-100 user can do his own work on the computer.

C. USING THE SPOOL PROGRAM

To use the printer, the user should type 'SPOOL' in the CCP level. Then there appears a guidance about the three options of the SPOOL program on the screen. The user can select any one of the three options by typing in the corresponding number of that option. The three options are listed below.

1. Interactive Print

When the user selects option 1, he can use the printer interactively. After the user press the Ctrl-P key, everything on the screen is copied to the printer through the Concentrator. This option ends when the user press the Ctrl-Z key.

2. Saving on a Disk File

When the user selects option 2, he can save the characters on the screen on the disk file. The user is asked to type in the file name. If the file name is not typed in, the default file name (TEMPFILE.\$\$\$) is used. After the user press the Ctrl-P key, everything on the screen is saved in the buffer. If the buffer size exceeds the limit, a warning message appears on the screen. In this case, the user should take an action as directed on the screen. This option ends when the user press the Ctrl-Z key, writing the buffer into the disk file.

3. Printing Existing Files

When the user selects option 3, he can print any existing file. The user is asked to type in the file name the user wants to print. After a file is printed out, another file can be printed continuously if the user wants to do.
